value of the regression line. For example, from the dataset, we have a 50 year-old person with systolic BP of 164 but the fitted-value from the regression line is 168.3 (see Fig. 2). Thus the residue for this person is -4.3 (164 - 168.4). For this dataset, we will have 55 residual points. For the linear regression model to be valid, there

Linear Regression Analysis: The statistical analysis employed to find out the exact position of the straight line is known as Linear regression analysis. From simple correlation analysis if there exist relationship between independent variable x and dependent variable y then the relationship can be expressed in a mathematical form known as Regression equation.

Recall that with linear regression, $\hat{E}(Y_i) = \beta_0 + \beta_1 X_i$ which might be a reasonable idea to apply to the count data; however, as seen above, if the mean of the distribution is modeled strictly as a linear function in $\hat{E}(X)$, then the line has the potential to predict negative counts and the variability will not be a function of $\hat{E}(X)$ if normal errors regression is used.

These methods derive from ridge regression (Hoerl and Kennard, 1970), a method for obtaining slightly biased but stabler estimates in linear models with highly correlated predictors. Finally, Altman and Royston (2000) give an excellent discussion of validating prediction models from a broader perspective, focusing on the ways in which these models may or may not be useful in clinical and other ...
